CSC 665: Homework 1

Chicheng Zhang

September 17, 2019

Please complete the following set of exercises on your own. The homework is due on Sep 26, 12:30pm, on Gradescope. You are free to cite existing theorems from the textbook and course notes.

Problem 1

For a random variable Z with mean $\mathbb{E}Z = 0$, we call Z is v-subgaussian, if

$$\psi_Z(t) = \ln \mathbb{E}e^{tZ} \le \frac{vt^2}{2}.$$

Show the following:

- 1. If Z has Gaussian distribution $N(0, \sigma^2)$, then Z is σ^2 -subgaussian.
- 2. If Z take values within interval [a,b], then Z is $\frac{(b-a)^2}{4}$ -subgaussian.
- 3. If Z_1, \ldots, Z_n are independent, and each Z_i is v_i subgaussian, then $\sum_{i=1}^n Z_i$ is $\sum_{i=1}^n v_i$ -subgaussian.
- 4. If Z is v-subgaussian, then

$$\mathbb{P}(|Z| \geq t) \leq 2 \exp \biggl\{ -\frac{t^2}{2v} \biggr\}.$$

Problem 2

In this exercise we give an alternative proof of the Chernoff bound for Bernoulli random variables: suppose X_1, \ldots, X_n are iid and from Bernoulli(p), define $\bar{X} = \sum_{i=1}^n X_i$, then,

$$\mathbb{P}(\bar{X} \ge q) \le \exp\{-n \operatorname{kl}(q, p)\}, q \ge p \tag{1}$$

$$\mathbb{P}(\bar{X} \le q) \le \exp\{-n \operatorname{kl}(q, p)\}, q \le p \tag{2}$$

1. Show that

$$\mathbb{P}(\bar{X} \ge q) = \sum_{m: m \ge nq} \binom{n}{m} p^m (1-p)^m.$$

2. Use the elementary inequality that $\binom{n}{m}q^m(1-q)^m \leq 1$, show that for $m \geq nq$,

$$\binom{n}{m}p^m(1-p)^m \le \left(\frac{p}{q}\right)^{nq} \left(\frac{1-p}{1-q}\right)^{n(1-q)}.$$

- 3. Use the above two items to conclude that $\mathbb{P}(\bar{X} \geq q) \leq n \exp\{-n \operatorname{kl}(q, p)\}$.
- 4. Note that compared to Equation 1, the above bound is has an additional factor of n on the right hand side. Use the elementary inequality $\sum_{m\geq nq}\binom{n}{m}q^m(1-q)^m\leq 1$ as a starting point, along with insights you gained from items 1 and 2 to show Equation (1).
- 5. Repeat the proof for the lower tail bound (Equation (2)).

Problem 3

In this exercise we will use basic concentration inequalities to show that, we can find exponentially many points on the unit sphere of \mathbb{R}^d that are far away from each other. Specifically, consider n random vectors X_1, X_2, \ldots, X_n in \mathbb{R}^d , where for each $i, X_i = \frac{1}{\sqrt{d}}(Z_{i,1}, \ldots, Z_{i,d})$. Here $\{Z_{i,j}\}_{i \in \{1,\ldots,n\}, j \in \{1,\ldots,d\}}$'s are all independent and identically distributed, and $Z_{i,j}$ takes value 1 with probability 1/2, and takes value -1 with probability 1/2.

- 1. Check that all X_i 's has unit length, i.e. $||X_i||_2 = 1$.
- 2. Use Hoeffding's Inequality to show that for any fixed pair $i, j \in \{1, ..., n\}, i \neq j$,

$$\mathbb{P}(|\langle X_i, X_j \rangle| \ge \frac{1}{2}) \le \exp\left\{-\frac{d}{8}\right\}.$$

3. Suppose $n = \exp\left\{\frac{d}{32}\right\}$. Show that with nonzero probability, for all pairs $i, j \in \{1, ..., n\}, i \neq j$, the angle between X_i and X_j is in $\left[\frac{\pi}{3}, \frac{2\pi}{3}\right]$.

Problem 4

Suppose D is a distribution over $[0,1] \times \{-1,+1\}$ such that D_X , the marginal of D over $\mathcal{X} = [0,1]$, is uniform. In addition,

$$P(Y = +1|x) = \begin{cases} 0 & x \le \frac{1}{2}, \\ 1 & x > \frac{1}{2} \end{cases},$$

i.e. the distribution is separable by a threshold classifier with threshold $\frac{1}{2}$. Suppose training examples $(X_1, Y_1), \ldots, (X_n, Y_n)$ are drawn iid from D. Now consider the following classifier \hat{h} :

$$\hat{h}(x) = \begin{cases} Y_i & x = X_i \text{ for some } i \in \{1, \dots, n\}, \\ -1 & \text{otherwise.} \end{cases}$$

(For simplicity, assume that all X_i 's are distinct, which also happens with probability 1.)

- 1. Calculate $\operatorname{err}(\hat{h}, S)$.
- 2. Calculate $\operatorname{err}(\hat{h}, D)$. What is the value of $\operatorname{err}(\hat{h}, S) \operatorname{err}(\hat{h}, D)$?
- 3. It may be tempting to use following argument to argue the concentration of $\operatorname{err}(\hat{h}, S)$ to $\operatorname{err}(\hat{h}, D)$. Define random variables $Z_i = \mathbf{1}(\hat{h}(X_i) \neq Y_i)$ for all i in $\{1, \ldots, n\}$, therefore, Hoeffding's inequality, with probability 1δ ,

$$|\operatorname{err}(\hat{h}, S) - \operatorname{err}(\hat{h}, D)| \le \sqrt{\frac{\ln \frac{1}{\delta}}{2n}}.$$

Does this contradict the results we got from item 2? Why?

Problem 5

In this exercise, we will unify the analysis of $O(\frac{1}{\epsilon})$ -style sample complexity for the realizable case and the $O(\frac{1}{\epsilon^2})$ -style sample complexity for the agnostic case, by revisiting the empirical risk minimization algorithm. Suppose \mathcal{H} is a finite hypothesis class, D is a distribution over labeled examples, and S is a training set of size m drawn iid from D. Denote by $\nu^* = \min_{h \in \mathcal{H}} \operatorname{err}(h, D)$ as the optimal generalization error, and \hat{h} the output of the empirical risk minimization algorithm.

1. Use Chernoff bound for Bernoulli random variables, show that for a fixed classifier h, with probability $1 - \delta$,

$$kl(err(h, S), err(h, D)) \le \frac{\ln \frac{2}{\delta}}{m}.$$

2. Use the above reasoning to conclude that with probability $1 - \delta$, for all classifiers h in \mathcal{H} ,

$$|\operatorname{err}(h,S) - \operatorname{err}(h,D)| \leq \sqrt{2 \max(\operatorname{err}(h,S),\operatorname{err}(h,D)) \frac{\ln \frac{2|\mathcal{H}|}{\delta}}{m}}.$$

(Hint: you can use the fact that $\mathrm{kl}(q,p) \geq \frac{(q-p)^2}{2\max(p,q)}$.)

3. Show that with probability $1 - \delta$, for all classifiers h in \mathcal{H} ,

$$\operatorname{err}(h, S) \le \operatorname{err}(h, D) + \sqrt{\operatorname{err}(h, D) \frac{2 \ln \frac{2|\mathcal{H}|}{\delta}}{m}} + \frac{2 \ln \frac{2|\mathcal{H}|}{\delta}}{m}.$$

(Hint: you can use the elementary fact that for $A, B, C > 0, A \le B + C\sqrt{A}$ implies $A \le B + C^2 + C\sqrt{B}$.)

4. Show that with probability $1 - \delta$, \hat{h} , the training error minimizer over \mathcal{H} , satisfies that

$$\operatorname{err}(\hat{h}, D) \le \nu^* + 6\sqrt{\frac{2\ln\frac{2|\mathcal{H}|}{\delta}}{m}\nu^*} + 8\frac{\ln\frac{2|\mathcal{H}|}{\delta}}{m}.$$

(Hint: you may find the following elementary facts useful: for A, B > 0, $\sqrt{AB} \le A + B$, $\sqrt{A + B} \le \sqrt{A} + \sqrt{B}$. If you get other constants on the right hand side, no worries - you will still get full credit.)

- 5. Conclude that:
 - (a) There exists a function m_A such that $m_A(\epsilon, \delta) = O(\frac{\ln |\mathcal{H}| + \ln \frac{1}{\delta}}{\epsilon^2})$, when $m \geq m_A(\epsilon, \delta)$, for all distributions D, $\operatorname{err}(\hat{h}, D) \leq \nu^* + \epsilon$ with probability 1δ .
 - (b) There exists a function m_R such that $m_R(\epsilon, \delta) = O(\frac{\ln |\mathcal{H}| + \ln \frac{1}{\delta}}{\epsilon})$, when $m \geq m_R(\epsilon, \delta)$, for all distributions D such that $\nu^* = 0$, $\operatorname{err}(\hat{h}, D) \leq \epsilon$ with probability 1δ .
